ABSTRACT

A multi-parametric version of the nonadditive entropy S_q is introduced. This new entropic form, denoted by $S_{a,b,r}$, possesses many interesting statistical properties, and it reduces to the entropy S_q for $b = 0$, $a = r := 1 - q$ (hence Boltzmann–Gibbs entropy S_{BG} for $b = 0$, $a = r \rightarrow 0$). The construction of the entropy $S_{a,b,r}$ is based on a general group-theoretical approach recently proposed by one of us, Tempesta (2016). Indeed, essentially all the properties of this new entropy are obtained as a consequence of the existence of a rational group law, which expresses the structure of $S_{a,b,r}$ with respect to the composition of statistically independent subsystems. Depending on the choice of the parameters, the entropy $S_{a,b,r}$ can be used to cover a wide range of physical situations, in which the measure of the accessible phase space increases say exponentially with the number of particles N of the system, or even stabilizes, by increasing N , to a limiting value.

1. Introduction

In the last decades, the non-extensive scenario, originally proposed in [1], has been largely investigated as a new thermodynamic framework allowing to generalize the standard Boltzmann–Gibbs approach to new physical contexts, where ergodicity hypothesis is violated [2]. At the same time, the ubiquity of the notion of entropy in social sciences paved the way to fruitful extensions of the standard information theory of Shannon and Khinchin [3–5] towards new classical and quantum formulations.

The search for new entropic forms has been very active in the last decades. Many different entropies have been proposed, generalizing the Boltzmann–Gibbs entropy from different perspectives (see, e.g., [6–17]).

In particular, a group-theoretical approach to the notion of entropy has been advocated in [14]. It is based on the observation that a thermodynamically admissible entropy should satisfy not only the first three Khinchin axioms (continuity, concavity, expansibility), but also a general *composability property*. It amounts to require that, given an entropic functional S , its values on a system defined by the union of two statistically independent subsystems A and B should depend (in addition to a possible set of fixed indices; for instance the index q for S_q) on the entropies of the two subsystems only. This requirement is motivated by the fact that entropy makes sense for macroscopic objects.

Composability can be imposed on full generality (and we shall talk about *strict composability* or *composability tout court*) or at least on subsystems characterized by the uniform distribution (composability in a *weak sense*). This last property applies, for instance, when considering isolated physical systems at the equilibrium (microcanonical ensemble), or in contact with a thermostat at very high temperature (canonical ensemble).¹ In full generality, it amounts to say that there exists a smooth function of two real variables $\Phi(x, y)$ such that (C1)

$$S(A \cup B) = \Phi(S(A), S(B); \{\eta\}) \quad (1)$$

where $\{\eta\}$ is a possible set of real continuous parameters, and $A \subset X$ and $B \subset X$ are two statistically independent subsystems of a given system X , with the further properties

(C2) Symmetry:

$$\Phi(x, y) = \Phi(y, x). \quad (2)$$

(C3) Associativity:

$$\Phi(x, \Phi(y, z)) = \Phi(\Phi(x, y), z). \quad (3)$$

(C4) Null-composability:

$$\Phi(x, 0) = x. \quad (4)$$

Note that the associativity property is crucial for the applicability of the zeroth law of thermodynamics. The Boltzmann–Gibbs, the S_q , the Rényi entropies and the non-trace form Z entropies [15] are known to be strictly composable. Instead, the weak composability property is shared by infinitely

¹ To be more precise, let us illustrate the BG case. The formula $S_{BG} = \ln W$ (assuming W to be finite) applies to both microcanonical and $T \rightarrow \infty$ canonical cases, but, in the former, W refers to the total number of states within a thin slice of phase space corresponding to a given total energy, whereas, in the latter, W refers to the total number of states within the entire phase space.

many more entropies. The theory of formal groups [18,19] offers a natural language for studying generalized entropies and treating the notion of composability. A huge class of entropies (continuous, concave, expansible, weakly composable) is provided by the *universal-group entropy* [14], related with the Lazard universal formal group [17]. This class possesses many remarkable properties, in particular extensivity in suitable regimes, Lesche stability (under mild hypotheses), among others.² The two most frequent examples of entropies of this class, i.e. possessing a group-theoretical structure, are Boltzmann–Gibbs entropy and S_q entropy. They have associated the additive group law

$$S(A \cup B) = S(A) + S(B) \quad (5)$$

and the multiplicative one [19]

$$S(A \cup B) = S(A) + S(B) + aS(A)S(B), \quad (6)$$

respectively. In the literature, $a \in \mathbb{R}$ is usually written in the form $a := 1 - q$.

In this paper, we explore a remarkable example of *rational composition law*:

$$S(A \cup B) = \frac{S(A) + S(B) + aS(A)S(B)}{1 + bS(A)S(B)}, \quad (7)$$

where $a, b \in \mathbb{R}$. The corresponding rational group law is given by

$$\Phi(x, y) = \frac{x + y + axy}{1 + bxy}. \quad (8)$$

Notice that when $a = b = 0$, we recover the standard additive law (5); for $b = 0$, we recover the case (6).

It is interesting to notice that for $b = 0$ this relation can be written in an additive form, namely

$$\frac{\ln |1 + a\Phi(x, y)|}{a} = \frac{\ln |1 + ax|}{a} + \frac{\ln |1 + ay|}{a}, \quad (9)$$

and this yields to Rényi entropy. Whenever $b \neq 0$, we have a genuinely new case. Notice that, for the particular instances $b = a + 1 \neq 0$ and $b = 1 - a \neq 0$, the following additive rules hold respectively:

$$\ln \left| \frac{1 - \Phi(x, y)}{1 + (a + 1)\Phi(x, y)} \right| = \ln \left| \frac{1 - x}{1 + (a + 1)x} \right| + \ln \left| \frac{1 - y}{1 + (a + 1)y} \right| \quad (10)$$

$$\ln \left| \frac{1 + \Phi(x, y)}{1 + (a - 1)\Phi(x, y)} \right| = \ln \left| \frac{1 + x}{1 + (a - 1)x} \right| + \ln \left| \frac{1 + y}{1 + (a - 1)y} \right|. \quad (11)$$

These two relations can be interchanged one into the other through the transformation $(x, a) \rightarrow (-x, -a)$. It might be interesting to explore these properties in future works.

The two-parametric rational group law (8) was first considered in [20], in the study of generalized cohomology theories. A specific one-parametric realization of it, i.e

$$\Phi(x, y) = \frac{x + y + (\alpha - 1)xy}{1 + \alpha xy} \quad (12)$$

plays an important role in algebraic topology. Precisely, for $\alpha = -1, 0, 1$, we obtain group laws respectively associated with the Euler characteristic, the Todd genus and the Hirzebruch L -genus [21]. Notice that identifying $a \equiv \alpha - 1$ and $b \equiv \alpha$, Eq. (8) turns out to be Eq. (12). Also, these relations between α, a and b are exactly the necessary conditions to get the additive property given in Eq. (10).

The aim of our work is to construct the entropy associated with the rational group law (8), or equivalently with the composition law (7). It is easy to verify that it satisfies Eqs. (2)–(4). Also, it admits an inverse, i.e. there exists a real function $\phi(x)$ such that

$$\Phi(x, \phi(x)) = 0. \quad (13)$$

² When dealing with composability, we will assume that the Boltzmann constant $k_B = 1$, as in [14,16]. Its explicit presence would produce a trivial change in the form of the composition law.

For instance, for the case of the additive law, $\phi(x) = -x$. For the rational group law (8) we have $\phi(x) = -x/(1 + ax)$. This is the reason why we talk about the group structure associated with an entropy [14]. Notice however that, if we restrict to values $x, y \in \mathbb{R}^+ \cup \{0\}$ (as mandatory for physically reasonable entropic forms), it is not possible to define an inverse.

Certainly, in complex systems we could conceive useful generalized entropic forms that are not even composable, mainly in social sciences for example, but this is not the subject of the present paper.

In the following, we shall construct explicitly the entropy associated with the law (8).

2. The construction of the entropy associated with the rational group law

In this section, we solve in full generality the following inverse problem: *given the group law (8), find the associated entropy*. Therefore, according to the general framework proposed in [14], assume that there exists a function

$$\Phi(x, y) = x + y + \text{higher order terms} \tag{14}$$

that satisfies the group properties (2)–(4). Notice that the rational law (8) is of this form. The entropy associated with (14) can be constructed as follows. We look for an invertible analytic function $G(t)$, such that

$$\Phi(x, y) = G(G^{-1}(x) + G^{-1}(y)). \tag{15}$$

This function $G(t)$ corresponds to the formal group exponential [19]. Here $G^{-1}(s)$ is the compositional inverse of $G(t)$, i.e. $G(G^{-1}(s)) = s$ and $G^{-1}(G(t)) = t$. The most general form of $G(t)$ we are looking for is the series

$$G(t) = \sum_{k=0}^{\infty} A_k \frac{t^{k+1}}{k+1} = A_0 t + A_1 \frac{t^2}{2} + A_2 \frac{t^3}{3} + \dots \tag{16}$$

The entropy associated will be of the form

$$S_U[p] := \sum_{i=1}^W p_i G\left(\ln \frac{1}{p_i}\right), \tag{17}$$

i.e. will be a representative of the *universal-group entropy* [14]; here $G(t)$ is supposed to guarantee the strict concavity of the function (17). The inverse $G^{-1}(s)$ as a formal series can be computed by means of the Lagrange inversion theorem. We get:

$$G^{-1}(s) = \frac{s}{A_0} - \frac{A_1}{2(A_0)^3} s^2 + \dots \tag{18}$$

The case of the BG entropy is immediately obtained. In this case $\Phi(x, y) = x + y$, and the Lazard law gives $G(t) = t$. From Eq. (17) we get back the BG case.

Let us apply the previous theory to the case of interest, i.e. the rational group law (8). Now we have that $A_k = A_k(a, b)$. The expansion of the function $\Phi(x, y)$ is

$$\begin{aligned} \Phi(x, y) = & x + y + axy - b(xy^2 + yx^2) - abx^2y^2 + b^2(x^2y^3 + x^3y^2) + ab^2x^3y^3 \\ & + \text{higher order terms.} \end{aligned} \tag{19}$$

By using the expression (15) with the form (16) for the expansion of the formal exponential, and identifying the terms appearing in this expansion with those coming from Eq. (19), we get an infinite set of relations for the coefficients A_k :

$$\begin{aligned} A_0 & \in \mathbb{R} \\ A_1 & = aA_0^2 \\ A_2 & = \frac{1}{2}(a^2 - 2b)A_0^3 \end{aligned}$$

$$A_3 = \frac{1}{3!} (a^3 - 8ab) A_0^4$$

$$A_4 = \frac{1}{4!} (a^4 - 22a^2b + 16b^2) A_0^5$$

$$A_5 = \frac{1}{5!} (a^5 - 52a^3b + 136ab^2) A_0^6$$

$$A_6 = \frac{1}{6!} (a^6 - 114a^4b + 720a^2b^2 - 272b^3) A_0^7 \quad (20)$$

$$\dots \quad (21)$$

A priori, the coefficients A_k provide the most general solution to our problem. Before proceeding further, let us consider the particular case $b = 0$. Then

$$\Phi(x, y) = x + y + axy. \quad (22)$$

If we put $b = 0$ in the previous coefficients (20), and let $A_0 = 1$, we get immediately

$$a_k = \frac{1}{k!} a^k \quad (23)$$

i.e.

$$G(t) = \frac{e^{at} - 1}{a}, \quad (24)$$

which is the correct form we were looking for. Indeed, according to the prescription (17), and putting $a = 1 - q$ we get back the S_q entropy

$$S = \sum_{i=1}^W p_i \frac{p_i^{q-1} - 1}{1 - q} = \frac{1 - \sum_{i=1}^W p_i^q}{q - 1}. \quad (25)$$

The general case provides us with a series solution: indeed, we reconstruct $G(t)$ and hence the entropy (17), term by term. However, this series can be expressed in a *closed form*, providing the solution

$$G(t) = \frac{2(e^{rt} - 1)}{-a(e^{rt} - 1) \pm \sqrt{a^2 + 4b}(e^{rt} + 1)} \quad (26)$$

where the range of the parameters a , b , r will be made precise in formulas (32)–(39). The function $G(t)$ in its space of parameters is monotonically increasing and non-negative, and is such that the associated entropy (17) is strictly concave. In particular it emerges that the arbitrary coefficient is fixed to be

$$A_0 = \pm \frac{r}{\sqrt{a^2 + 4b}}. \quad (27)$$

The solution in closed form (26) can also be obtained from the group law (8) by a direct procedure. It entails the formulation of a suitable ansatz for the solutions of (8).

The previous approach has the advantage of being systematic, i.e. it can be used in full generality starting from any group law of the form (14), and does not demand any guess or ansatz. This method amounts to the construction of a series solution for the functional equation (8), and is conceptually similar to the technique for generating series solutions of differential equations.

The realization of the universal-group entropy $\sum_i p_i G\left(\ln \frac{1}{p_i}\right)$ for $G(t)$ given by Eq. (26) is easily obtained, and is described below.

3. The new entropy and its properties

We shall present here, as a result of the previous approach, the explicit expression of the trace-form entropy corresponding to the group law (8). We will discuss this entropy in two slightly different versions, very related. The first one comes directly from the function $G(t)$ determined in Eq. (26). The

second one amounts to a change in the space of parameters, that for some aspects is possibly more adequate for a comparison with Boltzmann’s entropy.

3.1. The $S_{a,b,r}$ form

Definition 1. Let $\{p_i\}_{i=1,\dots,W}$, $W \geq 1$, with $\sum_{i=1}^W p_i = 1$, be a discrete probability distribution. The $S_{a,b,r}^{(+)}$ entropy, for $r > 0$, is the function

$$S_{a,b,r}^{(+)}[p] = \sum_{i=1}^W s^{(+)}[p_i] := \sum_{i=1}^W p_i \text{Log}_{a,b,r}^{(+)}\left(\frac{1}{p_i}\right), \tag{28}$$

where the generalized plus logarithm is defined as

$$\text{Log}_{a,b,r}^{(+)}(x) := \frac{2(x^r - 1)}{-a(x^r - 1) + \sqrt{a^2 + 4b}(x^r + 1)}, \quad x > 0. \tag{29}$$

The $S_{a,b,r}^{(-)}$ entropy, for $r < 0$, is the function

$$S_{a,b,r}^{(-)}[p] := \sum_{i=1}^W s^{(-)}[p_i] := \sum_{i=1}^W p_i \text{Log}_{a,b,r}^{(-)}\left(\frac{1}{p_i}\right), \tag{30}$$

where the generalized minus logarithm is given by

$$\text{Log}_{a,b,r}^{(-)}(x) := \frac{2(x^r - 1)}{-a(x^r - 1) - \sqrt{a^2 + 4b}(x^r + 1)}, \quad x > 0. \tag{31}$$

Here a, b are real parameters. Its range is defined by formulas (32)–(39) below.

These entropies satisfy many remarkable properties.

Proposition 2. The entropies (28) and (30) satisfy the first three Khinchin axioms.

Indeed, they are *continuous functions* of all their arguments. Second, the function $s^{(+)}[p]$, defined in Eq. (28) for $r > 0$, is concave, ensuring that the maximum of the entropy is attained at equiprobability, if the following conditions are satisfied for $W \geq 1$:

$$\text{(i) } 0 < r \leq 1 \quad \rightarrow a < 0 \quad \text{and} \quad b > \frac{-a^2}{4} \tag{32}$$

$$a \geq 0 \quad \text{and} \quad b > 0 \tag{33}$$

$$\text{(ii) } r > 1 \quad \rightarrow a \leq 0 \quad \text{and} \quad b > \frac{-a^2}{4} \tag{34}$$

$$a > 0 \quad \text{and} \quad b > \frac{a^2(r^2 - 1)}{4}. \tag{35}$$

Also, the function $s^{(-)}[p]$, defined in Eq. (30) for $r < 0$, is concave if the following conditions are verified for $W \geq 1$:

$$\text{(i) } -1 \leq r < 0 \quad \rightarrow a < 0 \quad \text{and} \quad b > \frac{-a^2}{4} \tag{36}$$

$$a \geq 0 \quad \text{and} \quad b > 0 \tag{37}$$

$$\text{(ii) } r < -1 \quad \rightarrow a \leq 0 \quad \text{and} \quad b > \frac{-a^2}{4} \tag{38}$$

$$a > 0 \quad \text{and} \quad b > \frac{a^2(r^2 - 1)}{4}. \tag{39}$$

Third, it is also possible to show that $p\text{Log}_{a,b,r}^{(\pm)}(1/p) \rightarrow 0$ when $p \rightarrow 0$, which ensures expansibility. Also, $\text{Log}_{a,b,r}^{(\pm)}(1) = 0$, yielding the value zero for the entropy when we have certainty.

Proposition 3. The generalized logarithms (29) and (31) satisfy the group law (7) and have the properties:

$$\text{Log}_{a,b,r}^{(+)}[p] = \text{Log}_{a,b,-r}^{(-)}[p], \quad (40)$$

$$\text{Log}_{a,b,-r}^{(\pm)}[p] = \text{Log}_{a,b,r}^{(\pm)}[1/p], \quad (41)$$

$$\text{Log}_{a,b,r}^{(+)}[p] = -\text{Log}_{-a,b,-r}^{(-)}[p] \quad (42)$$

implying that $\text{Log}_{a,b,r}^{(\pm)}[p] = -\text{Log}_{-a,b,-r}^{(\pm)}[p]$.

These equalities can be proven by direct calculations.

Proposition 4. The entropies $S_{a,b,r}^{(\pm)}$ reproduce the standard S_{BG} entropy for $b = 0$, $a = r$, in the limit $r \rightarrow 0$:

$$\lim_{r \rightarrow 0} S_{r,0,r}^{(\pm)}[p] = S_{BG}[p]. \quad (43)$$

Proof. Indeed, we have that

$$S_{a,0,r}^{(\pm)}[p] = \sum_{i=1}^W p_i \frac{p_i^{-|r|} - 1}{a}, \quad (44)$$

valid for any value of r . Therefore, for $a = r$ and taking the limit $r \rightarrow 0$, the previous expression converts into the entropy S_{BG} .

Constrained to the regions allowed in Proposition 2, the generalized logarithms $\text{Log}_{a,b,r}^{(\pm)}(W)$ are monotonically increasing functions of W , see Fig. 1. The graphics for the other allowed regions, shown in Proposition 2, have qualitatively the same behavior.

3.2. The $S_{a,b,c}$ form

Definition 5. Let $\{p_i\}_{i=1,\dots,W}$, $W \geq 1$, with $\sum_{i=1}^W p_i = 1$, be a discrete probability distribution. The $S_{a,b,c}^+$ entropy is the function defined, for $c > 0$, by

$$S_{a,b,c}^{(+)}[p] := \sum_{i=1}^W p_i \text{Log}_{a,b,c}^{(+)}\left(\frac{1}{p_i}\right), \quad (45)$$

where the generalized plus logarithm is defined as

$$\text{Log}_{a,b,c}^{(+)}(x) := \frac{2(x^c \sqrt{a^2+4b} - 1)}{-a(x^c \sqrt{a^2+4b} - 1) + \sqrt{a^2+4b}(x^c \sqrt{a^2+4b} + 1)}. \quad (46)$$

The entropy $S_{a,b,c}^-$ is defined in a perfectly analogous way.

In Definition 5, from the space of parameters (a, b, r) we have moved to the space (a, b, c) . The main motivation is that, with this simple reparametrization, the relation with the additive group law is more transparent. Indeed, for $a, b \rightarrow 0$ we recover it and the $S_{a,b,c}$ entropy converts into Boltzmann entropy, for any non-zero value of c , up to a global factor. In other words

$$\lim_{a \rightarrow 0, b \rightarrow 0} S^{(\pm)}(a, b, c) = cS_{BG},$$

coherently with the fact that, in this limit the group law (8) collapses into the additive group, corresponding to Boltzmann's entropy in the trace-form class. We remind that in many situations a

Fig. 1. $\text{Log}_{a,b,r}^{(+)}$ in function of W for $a = 0.3$, $b = 2$ and $r = 1.3$.

global factor is not important, as for example when we use the MaxEnt in order to get the equilibrium probability distribution.

Similarly, for $a \neq 0$, and $b \rightarrow 0$, the group law (8) converts into the multiplicative one, and the analysis can be repeated in agreement with formula (44).

The analysis of concavity for the entropic form $S_{a,b,c}$ as well as the discussion of many other properties, *mutatis mutandis* are obviously very similar to that of $S_{a,b,r}$ and are left to the reader.

The properties previously established ensure the interest and the plausibility of the entropies constructed in this Section. Indeed, they all satisfy the first three Khinchin axioms and the associated generalized logarithms are composable in the sense of Eqs. (1)–(4) (weak compossibility [14]).

4. On the extensivity of the entropy $S_{a,b,r}$

One of the main reasons to consider generalized entropies is the fact that they can be useful, or even mandatory, to describe systems with unusual behavior. If an entropy is extensive, it essentially means that, for an occupation law $W = W(N)$ of the phase space associated with a given system, it is asymptotically proportional to N , the number of particles of the system. Precisely, S_{BG} is extensive whenever $W(N) \sim k^N$, where $k \in \mathbb{R}_+$ is a suitable constant. However, for substantially different choices of $W = W(N)$, this property is no longer true for S_{BG} .

A natural question is to ascertain whether the new entropy we propose in this paper is extensive. Its group structure, once again, ensures that this property holds for a suitable asymptotic occupation law $W = W(N)$ of phase space. A general result proven in [14] is that a sufficient condition for an entropy of the form (17) to be extensive on the uniform distribution is that

$$\ln W(N) \sim G^{-1}(N), \tag{47}$$

provided that the real function $W(N)$ be defined for all $N \in \mathbb{N}$, with $\lim_{N \rightarrow \infty} W(N) = \infty$. These requirements usually restrict the space of parameters. In our case, we observe that when $p_i = 1/W$ for all $i = 1, \dots, W$, the entropies (28), for $r > 0$, and (30), for $r < 0$ tend to the limit value

$$S_{a,b,r}^{(\pm)}[1/W] \rightarrow \frac{2}{\sqrt{a^2 + 4b} - a}, \tag{48}$$

if $\lim_{N \rightarrow \infty} W(N) = \infty$. In particular, for $b \rightarrow 0$, the entropy diverges; as a consequence of the previous discussion, there exists a regime of extensivity, for $W(N) \sim N^\gamma$, with $\gamma = \frac{1}{a}$.

If $\lim_{N \rightarrow \infty} W(N) = d \in \mathbb{N}$, with $d > 1$, these entropies tend to the value

$$S_{a,b,r}^{(\pm)}[1/d] \rightarrow \frac{2(d^r - 1)}{\pm \sqrt{a^2 + 4b(d^r + 1) - a(d^r - 1)}}. \quad (49)$$

In both cases, if $b \neq 0$ the limiting value is finite, independently of whether W diverges or tends to a constant for $N \rightarrow \infty$. Consequently, the $b \neq 0$ entropies, albeit monotonically increasing functions of W , cannot be extensive.

If we look at the classification scheme proposed by Hanel and Thurner for the uniform distribution, we can see that this entropy, with $a, b \neq 0$, has scaling exponents $c = 1$ and $d = 0$, which is the same universality class as that of the entropy S_q , for $q > 1$ [8].

A natural question emerges, concerning the kind of systems such type of entropies could be useful for.³ A possible answer is that the present formalism could be relevant whenever treating systems highly connected, where the addition of a new degree of freedom essentially does not change the value of the entropy, for a large number of degrees of freedom. For example, if we add a molecule of water in a glass of liquid water, after enough time the molecule will move everywhere inside the glass. However, if we release a molecule of water in a glass filled with ice, the additional molecule will eventually freeze. The increase of the entropy value is substantially lower in the latter case than in the former.

One can also consider different scenarios, borrowed from social sciences, where no thermodynamical or energetical aspects are involved, and extensivity is a priori not required. Again such entropies, that increase very little with the addition of new degrees of freedom, could play a relevant role in describing situations where the amount of information tends to stabilize, irrespectively of the increase of new agents involved in the information exchange.

Consequently, the multiparametric entropy $S_{a,b,r}$ is compatible with both scenarios: the standard one, where an increase of the numbers of degrees of freedom converts into an increase of the entropy, and the “anomalous” one, where an increase of the number of particles essentially freezes the system, by confining it in the phase space. Excepting for S_q for $q > 1$ and S_δ for $\delta < 0$ (see [13] and references therein), this flexibility in the limit $W \rightarrow \infty$ is seemingly not shared by the entropies typically used in the literature.

³ Hereafter we shall focus on the entropic form $S_{a,b,r}$, since the same results are valid for $S_{a,b,c}$.
