#### Abstract

Focussing on a paradigmatic small system consisting of two coupled damped oscillators, we survey the role of the Lévy-Itô nature of the noise in the thermal conductance. For white noises, we prove that the Lévy-Itô composition (Lebesgue measure) of the noise is irrelevant for the thermal conductance of a non-equilibrium linearly coupled chain, which signals the independence between mechanical and thermodynamical properties. On the other hand, for the non-linearly coupled case, the two types of properties mix and the explicit definition of the noise plays a central role.

The law of heat conduction, or Fourier's law, is paramount in the description of systems where thermal equilibrium is absent [1]. The property that the heat flux density is equal to the product of the thermal conductivity by the negative temperature gradient [2] is a paradigmatic manifestation of the ubiquitous laws of thermodynamics [3]. This relevancy has stoked a significant amount of work on the derivation of the Fourier's law for large Hamiltonian systems [4-6]. Within this context, models with anharmonic coupling succeed in diffusing energy, but the analytic solutions thereto are very difficult to obtain, even for the few cases where that is possible. Because they allow a larger number of exactly solvable problems, small systems are a valid alternative [7] as well as particularly relevant in chemical physics and nanosystems [8]. In the scope of analytical methods to these systems, we highlight the averaging over time of observables of a system that endures a stationary state $[9,10]$. This account presents advantages compared with other methods, namely the Fokker-Planck approach. In particular, higher than second order cumulants of the noise are crucial to the correct solution to several problems, e.g., Poissonian [11] and other non-Gaussian massive particles [12]. In other words, systems where the interaction with a reservoir cannot be described by a Lévy process with a zero singular part of the measure when a LévyItô decomposition is applied [13]. Such cases are worthwhile as, e.g., Poisson (or shot-) noises are of primary importance[14, 15].

Stemming from the aforementioned facts, we perform a time averaging study utilising a small non-equilibrium system composed of two damped coupled oscillators at distinct temperatures and determine the explicit formula of the Fourier's law for linear and non-linear cases. In spite of its simplcity, the former has interesting features:

[^0]i) it is a pure non-equilibrium system; ii) Its heat flux definition is well known; iii) It is adjustable to different kinds of reservoirs; $i v$ ) It can be expanded into a infinite chain with a nearly direct application of the results of a $N=2$ block; $v$ ) It represents the result of Langevin coloured noises by a renormalisation of the masses [9] and $v i$ ) Linearity is still a source of important results in pure statistical and condensed matter problems [16-19].

Our problem focus on solving the set of equations,
$m \frac{d v_{i}(t)}{d t}=-k x_{i}(t)-\gamma v_{i}(t)-\sum_{l=1}^{2} k_{2 l-1}\left[x_{i}(t)-x_{j}(t)\right]^{2 l-1}+\eta_{i}(t)$
with $v_{i}(t) \equiv \frac{d x_{i}(t)}{d t}$, where $(i, j) \in\{1,2\}$ and $k_{1}$ and $k_{3}$ are the linear and non-linear coupling constants, respectively. The system is decoupled (linear) for $k_{1(3)}=0$. The transfer flux, $j_{12}(t)$, between the two particles reads,
$j_{12}(t) \equiv-\sum_{l=1}^{2} \frac{k_{2 l-1}}{2}\left[x_{1}(t)-x_{2}(t)\right]^{2 l-1}\left[v_{1}(t)+v_{2}(t)\right]$.
The term, $\eta_{i}(t)$, represents a general uncorrelated Lévy class stochastic process with cumulants,

$$
\begin{align*}
\left\langle\eta_{i_{1}}\left(t_{1}\right) \ldots \eta_{i_{n}}\left(t_{n}\right)\right\rangle_{c}= & \mathcal{A}\left(t_{1}, n\right) \delta_{i_{1} i_{2}} \ldots \delta_{i_{n-1} i_{n}} \times \\
& \delta\left(t_{1}-t_{2}\right) \ldots \delta\left(t_{n-1}-t_{n}\right) .(3) \tag{3}
\end{align*}
$$

From [20], we either have two or infinite non-zero cumulants. The former corresponds to the case in which the measure is absolutely continuous, characterising a Brownian process. In Eq. (3), $\mathcal{A}(t, n)$ is described by the noise; If it is Wiener-like, $W(t) \equiv \int_{t_{0}}^{t} \eta\left(t^{\prime}\right) d t^{\prime}, \mathcal{A}(t, n)$ is time-independent and equal to $\sigma^{2}$ for $n=2$ and zero otherwise ( $\sigma$ is the standard deviation of the Gaussian). Among infinite non-zero cumulant noises, we can include the Poisson process for which $\mathcal{A}(t, n)$ equals $\overline{\Phi^{n}} \lambda(t)$ [21], with $\Phi$ being the $p(\Phi)$ independent and identically distributed magnitude and $\lambda(t)$ the rate of shots. Herein,
$\mathcal{A}$ is time-independent without loss of generality. For $k_{1}=k_{3}=0$, Eq. (1) is totally decoupled and the solutions to the problem of homogeneous and sinusoidal
heterogeneous Poisson noises can be found in Ref. [11].
Laplace transforming $x_{i}(t)$ and $v_{i}(t)$ we obtain,

$$
\begin{gather*}
\tilde{x}_{i}(s)=\frac{k_{1}}{R(s)} \tilde{x}_{j}(s)+\frac{\tilde{\eta}_{i}(s)}{R(s)}+\frac{k_{3}}{R(s)} \lim _{\alpha \rightarrow 0} \iiint \frac{\prod_{n=1}^{3} \frac{d q_{n}}{2 \pi}\left[\tilde{x}_{i}\left(\mathrm{i} q_{n}+\alpha\right)-\tilde{x}_{j}\left(\mathrm{i} q_{n}+\alpha\right)\right]}{s-\left(\mathrm{i} q_{1}+\mathrm{i} q_{2}+\mathrm{i} q_{3}+3 \alpha\right)},  \tag{4}\\
s \tilde{x}_{i}(s)=\tilde{v}_{i}(s)
\end{gather*}
$$

$(\operatorname{Re}(s)>0)$ with $R(s) \equiv\left(m s^{2}+\gamma s+k+k_{1}\right)$. The solutions to Eq. (4) are obtained considering the relative position, $\tilde{r}_{D}(s) \equiv \tilde{x}_{1}(s)-\tilde{x}_{2}(s)$, the mid-point position, $\tilde{r}_{S}(s) \equiv\left(\tilde{x}_{1}(s)+\tilde{x}_{2}(s)\right) / 2$, as well as the respective noises $\tilde{\eta}_{D}(s) \equiv \tilde{\eta}_{1}(s)-\tilde{\eta}_{2}(s)$ and $\tilde{\eta}_{S}(s) \equiv$ $\left(\tilde{\eta}_{1}(s)+\tilde{\eta}_{2}(s)\right) / 2$. After some algebra it yields,

$$
\left\{\begin{array}{c}
\tilde{r}_{D}(s)=\frac{\tilde{\eta}_{D}(s)}{R^{\prime}(s)}-\frac{2 k_{3}}{R^{\prime}(s)} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{+\infty} \frac{\prod_{l=1}^{3} \frac{d q_{l}}{2 \pi} \tilde{r}_{D}\left(\mathrm{i} q_{l}+\alpha\right)}{s-\sum_{l=1}^{3}\left(\mathrm{i} q_{l}+\alpha\right)}  \tag{5}\\
\tilde{r}_{S}=\frac{\tilde{\eta}_{S}(s)}{R^{\prime \prime}(s)}
\end{array}\right.
$$

with $R^{\prime}(s) \equiv\left(m s^{2}+\gamma s+k+2 k_{1}\right)$ and $R^{\prime \prime}(s) \equiv$ $\left(m s^{2}+\gamma s+k\right)$. Reverting Eq. 5 we get $\tilde{x}_{1}(s)$ and $\tilde{x}_{2}(s)$. Concomitantly, we must compute the Laplace transforms of $\eta_{1}$ and $\eta_{2}$,

$$
\begin{align*}
\left\langle\tilde{\eta}_{i_{1}}\left(z_{1}\right) \ldots \tilde{\eta}_{i_{n}}\left(z_{n}\right)\right\rangle_{c}= & \int_{0}^{\infty} \prod_{j=1}^{n} d t_{i_{j}} \exp \left[-\sum_{j=1}^{n} z_{i_{j}} t_{i_{j}}\right] \\
& \times\left\langle\eta_{i_{1}}\left(t_{1}\right) \ldots \eta_{i_{n}}\left(t_{n}\right)\right\rangle_{c} \\
= & \frac{\mathcal{A}(n)}{\sum_{j=1}^{n} z_{i_{j}}} \delta_{i_{1} i_{2}} \ldots \delta_{i_{n-1} i_{n}} . \tag{6}
\end{align*}
$$

that are employed in the averages over time [9],

$$
\begin{align*}
\overline{\left\langle x_{a}^{m} v_{b}^{n}\right\rangle_{c}} & =\lim _{z \rightarrow 0} z \iiint \delta\left(t-t_{1}\right) \delta\left(t-t_{2}\right) \mathrm{e}^{-z t}\left\langle x_{a}^{m}\left(t_{1}\right) v_{b}^{n}\left(t_{2}\right)\right\rangle_{c} d t_{1} d t_{2} d t  \tag{7}\\
& =\lim _{z, \varepsilon \rightarrow 0} \int_{-\infty}^{\infty} \prod_{l=1}^{m+n} \frac{d q_{l}}{2 \pi} z \frac{\prod_{l^{\prime}=1}^{n}\left(\mathrm{i} q_{l^{\prime}}+\varepsilon\right)\left\langle\prod_{l=1}^{m+n} \tilde{x}\left(\mathrm{i} q_{l}+\varepsilon\right)\right\rangle_{c}}{z-\left(\sum_{l^{\prime}=1}^{m+n} \mathrm{i} q_{l^{\prime}}+(m+n) \varepsilon\right)} \tag{8}
\end{align*}
$$

Allowing for a contour that goes along the straight line from $-\rho+\mathrm{i} \varepsilon$ to $\rho+\mathrm{i} \varepsilon$ and then counterclockwise along a semicircle centered at $0+\mathrm{i} \varepsilon$ from $\rho+\mathrm{i} \varepsilon$ to $-\rho+\mathrm{i} \varepsilon$ ( $\rho \rightarrow \infty$ and $\varepsilon \rightarrow 0$ ), we realise that two situations occur: either the calculation of the residues leads us to a term like $\frac{z}{z-w} u$, with $(u, w) \neq 0$, which vanishes in the limit $z \rightarrow 0$, or to $\frac{z}{z} u$, which is non-zero. The problem solving now resumes to an expansion of Eq. (2) in powers of $k_{3}$ (see Appendices). Hereinafter, we show the results of two typical cases of reservoirs with either fully continuous or singular measures. In first order on $k_{3}$, the transfer flux reads,

$$
\begin{equation*}
\overline{\left\langle j_{12}\right\rangle}=\overline{\left\langle j_{12}^{(0)}\right\rangle}+\overline{\left\langle j_{12}^{(1)}\right\rangle}+\overline{\left\langle j_{12}^{(s)}\right\rangle}+\mathcal{O}\left(k_{3}^{2}\right), \tag{9}
\end{equation*}
$$

with,

$$
\left\{\begin{array}{c}
\overline{\left\langle j_{12}^{(0)}\right\rangle}=-\frac{k_{1}^{2}}{4} \frac{\left[\mathcal{A}_{1}(2)-\mathcal{A}_{2}(2)\right]}{m k_{1}^{2}+\gamma^{2}\left(k+k_{1}\right)}  \tag{10}\\
\overline{\left\langle j_{12}^{(1)}\right\rangle}=-\frac{3}{8} \gamma k_{1} k_{3} \frac{\left(2 k+k_{1}\right)\left[\mathcal{A}_{1}(2)^{2}-\mathcal{A}_{2}(2)^{2}\right]}{\left(k+2 k_{1}\right)\left[\gamma^{2}\left(k+k_{1}\right)+m k_{1}^{2}\right]^{2}}
\end{array}\right.
$$

and

$$
\begin{equation*}
\overline{\left\langle j_{12}^{(s)}\right\rangle}=-\frac{27}{2} \gamma^{2} \frac{k_{1} k_{3}}{\lambda} \frac{\mathcal{N}}{\mathcal{D}}\left(\left[\mathcal{A}_{1}(2)^{2}-\mathcal{A}_{2}(2)^{2}\right]\right) \tag{11}
\end{equation*}
$$

for the Poisson case, which represents a hallmark of the singular measure noise, and $\overline{\left\langle j_{12}^{(s)}\right\rangle}=0$ for the Brownian case. It is clear that when $k_{1} k_{3} / \lambda \ll 1$, the weight of the singularity of the noise measure gets its importance reduced and the Poissonian result approaches that of the Brownian. The coefficients in Eq. (11) are,

$$
\begin{align*}
\mathcal{N} \equiv & \gamma^{2}\left(5 k+3 k_{1}\right)+m\left(3 k_{1}^{2}+4 k^{2}+11 k k_{1}\right),  \tag{12}\\
\mathcal{D} \equiv & {\left[m\left(4 k+9 k_{1}\right)^{2}+6 \gamma^{2}\left(2 k+3 k_{1}\right)\right] \times }  \tag{13}\\
& {\left[3 \gamma^{4}+m^{2} k_{1}^{2}+4 m \gamma^{2}\left(k+k_{1}\right)\right]\left[\gamma^{2}\left(k+k_{1}\right)\right] }
\end{align*}
$$

Thence, we are finally in the position to compute the
thermal conductance,

$$
\begin{align*}
\kappa & \equiv-\frac{\partial}{\partial \Delta T}\left\langle j_{12}\right\rangle_{\Delta T}  \tag{14}\\
\kappa & =-\frac{\overline{\left\langle j_{12}\right\rangle}}{T_{1}-T_{2}}
\end{align*}
$$

Resorting to single particle results and the equipartition theorem [11], we relate the cumulant features of the noise and the proper temperature, $T_{i}$, namely, $\mathcal{A}_{i}(2)=2 \gamma T_{i}$, yielding a thermal conductance, $\kappa=\kappa^{(0)}+\kappa^{(1)}+\kappa^{(s)}+$ $\mathcal{O}\left(k_{3}^{3}\right)$. Equations (9)-(11) pave the way to the following assertion; When interacting particles are subject to white reservoirs and coupled in a linear form, the explicit thermal conductance is independent of the specific nature of the noise, namely the outcome of their Lévy-Itô decomposition, whereas for non-linear coupling the nature of the measure of the noise (its decomposition) is pivotal. In other words, the linear case is heedless of the continuous or singular measure of the fluctuations taking only into consideration the temperatures of the reservoirs. Hence, $\kappa^{(0)}$ is exactly the same, either we have a Wiener noise (continuous measure) [10, 22] or a Poisson noise (singular measure). Although in the linear coupling case we have only explicitly proved it for two particles, the result is valid for general $N$. In fact, for a linear chain, the local energy flow $\left\langle j_{i, i+1}\right\rangle$ can be clearly written as a function of the cumulants $\left\langle\eta_{i}(z) \eta_{1}\left(z^{\prime}\right)\right\rangle_{c}=2 \gamma T_{i}$ and $\left\langle\eta_{i+1}(z) \eta_{i+1}\left(z^{\prime}\right)\right\rangle_{c}=2 \gamma T_{i+1}$, wherein the dependence on the specific nature of the noise is eliminated, except for the respective temperatures. On the other hand, it is flat that if the nature of the noise affects the thermal conductance of the simplest coupling element, the same influence for generic chains is certain. Bearing in mind single particle results, it would be expected that the dependence on the Lévy-Itô nature of the reservoirs would have already appeared in linearly coupled systems. Instead, the essence of the noise does only turn out relevant when the interaction between the elements of the system happens in a non-linear way. Only in this case higher order cumulants, which can be understood as higher-order sources of energy, of the characteristic function of noise intervene and affect the result $[11,12]$. For the same $\left(k_{1}, k_{3}\right)$, as we decrease the singularity by soaring $\lambda$, the two thermal conductances match one another.

To illustrate these results, we have simulated different cases of equally massive particles subject to Wiener and Poisson noises at different temperatures, $T$. For the former, we have $T=\sigma^{2} / 2$ whereas for the latter, we have assumed a homogeneous Poisson process with a rate of events $\lambda$, with a random amplitude, $\Phi$, exponentially distributed, $p(\Phi) \sim \exp [-\Phi / \bar{\Phi}]$, which yields $T=\lambda_{0} \bar{\Phi}^{2} / \gamma[11]$. In Fig. 1, we depict linear coupling. It is visible that after a transient time, $t^{*}$, the system reaches a stationary state and $\left\langle j_{12}\right\rangle$ becomes equal to $\overline{\left\langle j_{12}\right\rangle}$, whatever the reservoirs. In fact, even more complex models, such as linear chains of oscillators, verify the $\kappa=\kappa^{(0)}$ property. Still, this is valid when each particle is perturbed by different types of noise, e.g., a Brownian
particle coupled with a Poissonian particle. The instance where the noises are of different nature gives rise to an apparent larger value of the standard deviation. ${ }^{1}$

FIG. 1. (Colour on-line) Average exchange flux $\left\langle j_{12}\right\rangle$ of a two massive particle system for different combinations of paradigmatic types of noise with $T_{1}=10$ and $T_{2}=121 / 10, m=10$, $\gamma=k=1, k_{1}=1 / 5, k_{3}=0$ and $\lambda=10$ for Poissonian particles. After the trasient, $\kappa$ agrees with the theoretical value, $\kappa=21 / 800=0.02625$, with the fitting curves lying within line thickness. The averages have been obtained averaging over $850 \times\left(5 \times 10^{5}\right)$ points. The discretisation used is $\delta t=10^{-5}$ with snapshots at every $\Delta t=10^{-3}$.

In turning $k_{3} \neq 0$, the composition of the measure of the reservoirs comes into play. In Fig. 2, we show the difference between equivalent Brownian and Poissonian particles with a good agreement between the averages over numerical realisations and the respective (first order) approximation. For the same temperature, the larger the value of $k$, the larger the value of $k_{3}^{*}$ defining a $10 \%$ difference between numerical values the approximation.

To summarise, we have studied the thermal conduction in a paradigmatic mechanical system composed of two coupled damped harmonic oscillators subject to generic noises, which can be understood as a concise way to describe non-equilibrium problems. By averaging in the Laplace space, we have been able to determine the thermal conductance of a linearly coupled system and approximate formulae for non-linearly coupled particles. We have shown the thermal conductance of the former is independent of the nature of the (white) noise, namely its Lévy-Itô decomposition structure. This result is unexpected since the measure of the thermal bath plays a major role for single particle properties. The dependence on the noise only emerges when there exists transfer of

[^1]

FIG. 2. (Colour on-line) Comparison between numerically obtained values (symbols) and the first order approximation of thermal conductance from Eqs. (9)-(11) for different temperatures pairs, namely $A=\left\{10, \frac{169}{10}\right\}, B=\left\{10, \frac{225}{10}\right\}$, $\mathrm{C}=\left\{10, \frac{289}{10}\right\}$ with $m=10, \gamma=k=1, k_{1}=1 / 5, k_{3}=0$ and $\lambda=1$ for Poissonian particles.
energy in a non-linear way and higher-order cumulants of the noise enter in the calculations. In the case of Poisson noises, we show that the difference to Brownian noises becomes negligeble when the ratio between the coupling constants and the rate of events is small. Our calculations evidence the independence of the thermodynamical properties of the system from the nature of the reservoirs in linearly coupled systems. On the other hand, when the coupling is non-linear, the nature of the reservoirs affects
the thermal conductance, which represents a mixture between mechanic and thermodynamical properties of the system.

Our results have direct implication for the study of the thermal conductance of systems under the influence of noises other than Wiener, for instance: i) solid state problems wherein shot (singular measure) noise is related to the quantisation of the charge [23]; ii) RLC circuits with injection of power at some rate resembling heat pumps [14]; iii) Surface diffusion and low vibrational motion with adsorbates, e.g., $\mathrm{Na} / \mathrm{Cu}(001)$ compounds [25]; iv) Biological motors in which shot noise mimics the nonequilibrium stochastic hydrolysis of adenosine triphosphate [15] and v) Molecular dynamics when the Andersen thermostat is applied. Actually, in molecular dynamics [24], the Langevin reservoir is just one in a large collection of baths represented by our definition of noise (3). In these problems, for nonlinearly coupled elements the experimentally measured energy flux will be greater than the energy flux given by Langevin reservoirs at the same temperatures and equal if coupling is linear.

## ACKNOWLEDGMENTS

We would like to thank the partial funding from Faperj and CNPq (W.A.M.M.) and the European Commission through the Marie Curie Actions FP7-PEOPLE-2009IEF (contract nr 250589) (S.M.D.Q.). Diogo O. SoaresPinto is acknowledged for early discussions on this subject.

## Appendix A: Heat flux definition

As indicated in the main document the model consists of two masses connected by linear and non-linear springs so that,

$$
\begin{align*}
\dot{x}_{1} & = & v_{1} \\
\dot{x}_{2} & = & v_{2} \\
m \ddot{x}_{1} & = & -k x_{1}-k_{1}\left(x_{1}-x_{2}\right)-k_{3}\left(x_{1}-x_{2}\right)^{3}-\gamma \dot{x}_{1}+\eta_{1}  \tag{A1}\\
m \ddot{x}_{2} & = & -k x_{2}-k_{1}\left(x_{2}-x_{1}\right)-k_{3}\left(x_{2}-x_{1}\right)^{3}-\gamma \dot{x}_{2}+\eta_{2}
\end{align*}
$$

The flux of energy $J_{1 \rightarrow 2}$ defines the thermal conductance. For this unidimensional mechanical system, the transmitted power is by the the instantaneous power difference [10]:

$$
\begin{equation*}
J_{1 \rightarrow 2}=\frac{d W_{1 \rightarrow 2}-d W_{2 \rightarrow 1}}{2 d t}=\frac{F_{1 \rightarrow 2} v_{2}-F_{2 \rightarrow 1} v_{1}}{2} \tag{A2}
\end{equation*}
$$

where $F_{\alpha \rightarrow \beta}$ is the force exerted on particle $\beta$ by particle $\alpha$.
Assuming a conservative potential, the form of the force between the particles will be,

$$
\begin{equation*}
F_{\alpha \rightarrow \beta}=-k_{1}\left(x_{\alpha}-x_{\beta}\right)-k_{3}\left(x_{\alpha}-x_{\beta}\right)^{3} \tag{A3}
\end{equation*}
$$

Our goal is to derive a systematic expansion for the time-average $j_{12} \equiv\left\langle J_{1 \rightarrow 2}\right\rangle \equiv \kappa\left(T_{2}-T_{1}\right)$, where $\kappa$ is the thermal
conductance of the model. Thus, we can write

$$
\begin{array}{rlc}
j_{12} & = & \left\langle\frac{F_{1 \rightarrow 2} v_{2}-F_{2 \rightarrow 1} v_{1}}{2}\right\rangle \\
& =-k_{1}\left\langle\frac{x_{1} v_{2}-x_{2} v_{1}}{2}\right\rangle-k_{3}\left\langle\frac{\left(x_{1}-x_{2}\right)^{3}\left(v_{2}+v_{1}\right)}{2}\right\rangle \tag{A4}
\end{array}
$$

where the terms of the form $<x_{1}^{n} v_{1}>$ and $<x_{2}^{n} v_{2}>$ vanish identically as $t \rightarrow \infty$ [10].

## 1. The Gaussian case

The noise functions are assumed to be white and Gaussian,

$$
\begin{array}{rlc}
<\eta_{1}\left(t_{1}\right)>_{c} & = & 0, \\
<\eta_{1}\left(t_{1}\right) \eta_{1}\left(t_{2}\right)_{c} & = & 2 \gamma T_{1} \delta\left(t_{1}-t_{2}\right), \\
<\eta_{2}\left(t_{1}\right)>_{c} & = & 0,  \tag{A5}\\
<\eta_{2}\left(t_{1}\right) \eta_{2}\left(t_{2}\right)>_{c} & = & 2 \gamma T_{2} \delta\left(t_{1}-t_{2}\right),
\end{array}
$$

The initial conditions will be assumed to be

$$
\begin{equation*}
x_{1}(0)=v_{1}(0)=x_{2}(0)=v_{2}(0)=0 \tag{A6}
\end{equation*}
$$

The Laplace transforms read,

$$
\begin{align*}
& \tilde{v}_{1}(s)=s \tilde{x}_{1}(s), \\
& \tilde{v}_{2}(s)=s \tilde{x}_{2}(s) \tag{A7}
\end{align*}
$$

using $R(s) \equiv\left(m s^{2}+\gamma s+\left(k+k_{1}\right)\right)=m\left(s^{2}+\theta s+\omega^{2}\right)=\left(s-\zeta_{+}\right)\left(s-\zeta_{-}\right)$, where

$$
\begin{equation*}
\zeta_{ \pm}=-\frac{\theta}{2} \pm \frac{i}{2} \sqrt{4 \omega^{2}-\theta^{2}} \tag{A8}
\end{equation*}
$$

we have,

$$
\begin{align*}
\tilde{x}_{1}(s)= & \frac{k_{1}}{R(s)} \tilde{x}_{2}(s)+\frac{\tilde{\eta}_{1}(s)}{R(s)}-\frac{k_{3}}{R(s)} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{+\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{2}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{3}}{2 \pi} \times  \tag{A9}\\
& \times \frac{\left(\tilde{x}_{1}\left(i q_{1}+\alpha\right)-\tilde{x}_{2}\left(i q_{1}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{2}+\alpha\right)-\tilde{x}_{2}\left(i q_{2}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{3}+\alpha\right)-\tilde{x}_{2}\left(i q_{3}+\alpha\right)\right)}{s-\left(i q_{1}+i q_{2}+i q_{3}+3 \alpha\right)}
\end{align*}
$$

and

$$
\begin{align*}
\tilde{x}_{2}(s)= & \frac{k_{1}}{R(s)} \tilde{x}_{1}(s)+\frac{\tilde{\eta}_{2}(s)}{R(s)}+\frac{k_{3}}{R(s)} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{+\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{2}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{3}}{2 \pi} \times  \tag{A10}\\
& \times \frac{\left(\tilde{x}_{1}\left(i q_{1}+\alpha\right)-\tilde{x}_{2}\left(i q_{1}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{2}+\alpha\right)-\tilde{x}_{2}\left(i q_{2}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{3}+\alpha\right)-\tilde{x}_{2}\left(i q_{3}+\alpha\right)\right)}{s-\left(i q_{1}+i q_{2}+i q_{3}+3 \alpha\right)}
\end{align*}
$$

An straightforward way to write a recurrence equation for the problem above is to take the difference:

$$
\begin{align*}
\left(1+\frac{k_{1}}{R(s)}\right)\left(\tilde{x}_{1}(s)-\tilde{x}_{2}(s)\right)= & \frac{\tilde{\eta}_{1}(s)-\tilde{\eta}_{2}(s)}{R(s)}-\frac{2 k_{3}}{R(s)} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{+\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{2}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{3}}{2 \pi} \times  \tag{A11}\\
& \times \frac{\left(\tilde{x}_{1}\left(i q_{1}+\alpha\right)-\tilde{x}_{2}\left(i q_{1}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{2}+\alpha\right)-\tilde{x}_{2}\left(i q_{2}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{3}+\alpha\right)-\tilde{x}_{2}\left(i q_{3}+\alpha\right)\right)}{s-\left(i q_{1}+i q_{2}+i q_{3}+3 \alpha\right)}
\end{align*}
$$

Defining $R^{\prime}(s) \equiv\left(m s^{2}+\gamma s+\left(k+2 k_{1}\right)\right)=\left(s^{2}+\theta s+\omega_{1}^{2}\right)=\left(s-\zeta_{1+}\right)\left(s-\zeta_{1-}\right)$, where,

$$
\zeta_{1 \pm}=-\frac{\theta}{2} \pm \frac{i}{2} \sqrt{4 \omega_{1}^{2}-\theta^{2}}
$$

we obtain the difference,

$$
\begin{array}{rc}
\tilde{r}_{D}= & \tilde{x}_{1}(s)-\tilde{x}_{2}(s) \\
= & \frac{\tilde{\eta}_{1}(s)-\tilde{\eta}_{2}(s)}{R^{\prime}(s)}-\frac{2 k_{3}}{R^{\prime}(s)} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{+\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{2}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{3}}{2 \pi} \times  \tag{A12}\\
& \times \frac{\left(\tilde{x}_{1}\left(i q_{1}+\alpha\right)-\tilde{x}_{2}\left(i q_{1}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{2}+\alpha\right)-\tilde{x}_{2}\left(i q_{2}+\alpha\right)\right)\left(\tilde{x}_{1}\left(i q_{3}+\alpha\right)-\tilde{x}_{2}\left(i q_{3}+\alpha\right)\right)}{s-\left(i q_{1}+i q_{2}+i q_{3}+3 \alpha\right)} .
\end{array}
$$

Defining $R^{\prime \prime}(s) \equiv\left(m s^{2}+\gamma s+k\right)=\left(s^{2}+\theta s+\omega_{2}^{2}\right)=\left(s-\zeta_{2+}\right)\left(s-\zeta_{2-}\right)$, where,

$$
\zeta_{2 \pm}=-\frac{\theta}{2} \pm \frac{i}{2} \sqrt{4 \omega_{2}^{2}-\theta^{2}}
$$

we obtain the sum as,

$$
\begin{align*}
\tilde{r}_{S} & =\frac{\tilde{x}_{1}(s)+\tilde{x}_{2}(s)}{2} \\
& =\frac{\tilde{\eta}_{1}(s)+\tilde{\tilde{\eta}}_{2}(s)}{2 R^{\prime \prime}(s)} \tag{A13}
\end{align*}
$$

Inverting the relations it yields,

$$
\begin{align*}
& \tilde{x}_{1}(s)=\tilde{r}_{S}+\frac{\tilde{r}_{D}}{2} \\
& \tilde{x}_{2}(s)=\tilde{r}_{S}-\frac{\tilde{r}_{D}}{2} \tag{A14}
\end{align*}
$$

In the same way, we can define the difference and the average of the noise as,

$$
\begin{align*}
& \tilde{\eta}_{S}(s)=\frac{\tilde{\eta}_{1}+\tilde{\eta}_{2}}{2}  \tag{A15}\\
& \tilde{\eta}_{D}(s)=\tilde{\eta}_{1}-\tilde{\eta}_{2}
\end{align*}
$$

We can now express the recurrence relations for the new variables,

$$
\begin{aligned}
\tilde{r}_{D}(s)= & \frac{\tilde{\eta}_{D}(s)}{R^{\prime}(s)}-\frac{2 k_{3}}{R^{\prime}(s)} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{+\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{2}}{2 \pi} \int_{-\infty}^{+\infty} \frac{d q_{3}}{2 \pi} \times \\
& \times \frac{\tilde{r}_{D}\left(i q_{1}+\alpha\right) \tilde{r}_{D}\left(i q_{2}+\alpha\right) \tilde{r}_{D}\left(i q_{3}+\alpha\right)}{s-\left(i q_{1}+i q_{2}+i q_{3}+3 \alpha\right)} \\
\tilde{r}_{S}= & \frac{\tilde{\eta}_{S}(s)}{R^{\prime \prime}(s)}
\end{aligned}
$$

The Laplace transforms of the noise are,

$$
\begin{align*}
& <\tilde{\eta}_{D}\left(s_{1}\right) \tilde{\eta}_{D}\left(s_{2}\right)>_{c}=\frac{2 \gamma\left(T_{1}+T_{2}\right)}{s_{1}+s_{2}} \\
& <\tilde{\eta}_{S}\left(s_{1}\right) \tilde{\eta}_{S}\left(s_{2}\right)>_{c}=\frac{\gamma\left(T_{1}+T_{2}\right)}{2\left(s_{1}+s_{2}\right)}  \tag{A17}\\
& <\tilde{\eta}_{S}\left(s_{1}\right) \tilde{\eta}_{D}\left(s_{2}\right)>_{c}=\frac{\gamma\left(T_{1}-T_{2}\right)}{s_{1}+s_{2}}
\end{align*}
$$

## Appendix B: Heat conductance

## 1. General expression

The series expansion for the thermal flux reads,

$$
\begin{equation*}
j_{12}=-\frac{k_{1}}{2}\left\langle\left(x_{1}-x_{2}\right)\left(v_{2}+v_{1}\right)\right\rangle-\frac{k_{3}}{2}\left\langle\left(x_{1}-x_{2}\right)^{3}\left(v_{2}+v_{1}\right)\right\rangle \tag{B1}
\end{equation*}
$$

We can write $(a, b=1,2)$,

$$
\begin{align*}
\overline{\left\langle x_{a}^{m} v_{b}^{n}\right\rangle_{c}} & =\lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \prod_{k=1}^{m} \frac{d q_{k}}{2 \pi} \int_{-\infty}^{\infty} \prod_{l=1}^{n} \frac{d q_{l}}{2 \pi} \frac{z}{z-\left(\sum_{k=1}^{m} i q_{k}+\sum_{l=1}^{n} i q_{l}+(m+n) \epsilon\right)}\left\langle\prod_{k=1}^{m} \tilde{x}\left(i q_{k}+\epsilon\right) \prod_{l=1}^{n} \tilde{v}\left(i q_{l}+\epsilon\right)\right\rangle_{c} \\
& =\lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \prod_{k=1}^{m+n} \frac{d q_{k}}{2 \pi} \frac{z}{z-\left(\sum_{k=1}^{m+n} i q_{k}+(m+n) \epsilon\right)} \prod_{l=1}^{n}\left(i q_{l}+\epsilon\right)\left\langle\prod_{k=1}^{m+n} \tilde{x}\left(i q_{k}+\epsilon\right)\right\rangle_{c} . \tag{B2}
\end{align*}
$$

We can thus express the heat flux $\overline{\left\langle j_{12}\right\rangle}$ as,

$$
\begin{gather*}
\overline{\left\langle j_{12}\right\rangle}=-k_{1} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{\infty} \frac{d q_{2}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)}\left(i q_{2}+\epsilon\right)\left\langle\tilde{r}_{D}\left(i q_{1}+\epsilon\right) \tilde{r}_{S}\left(i q_{2}+\epsilon\right)\right\rangle_{c}- \\
-k_{3} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{\infty} \frac{d q_{2}}{2 \pi} \int_{-\infty}^{\infty} \frac{d q_{3}}{2 \pi} \int_{-\infty}^{\infty} \frac{d q_{4}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+i q_{3}+i q_{4}+2 \epsilon\right)} \times  \tag{B3}\\
\times\left\{\left(i q_{4}+\epsilon\right)\left\langle\tilde{r}_{D}\left(i q_{1}+\epsilon\right) \tilde{r}_{D}\left(i q_{2}+\epsilon\right) \tilde{r}_{D}\left(i q_{3}+\epsilon\right) \tilde{r}_{S}\left(i q_{4}+\epsilon\right)\right\rangle_{c}\right\} .
\end{gather*}
$$

We now proceed to expand the heat flow in powers of $k_{3}$.

## 2. Order zero on $k_{3}$

The order zero term is,

$$
\begin{aligned}
\overline{\left\langle j_{12}\right\rangle_{0}} & =\quad-k_{1} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{\infty} \frac{d q_{2}}{2 \pi} \frac{z\left(i q_{2}+\epsilon\right)}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)} \frac{\left\langle\tilde{\eta}_{D}\left(i q_{1}+\epsilon\right) \tilde{\eta}_{S}\left(i q_{2}+\epsilon\right)\right\rangle_{c}}{R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime \prime}\left(i q_{2}+\epsilon\right)} \\
& =\quad-\frac{k_{1}}{m^{2}} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{\infty} \frac{d q_{2}}{2 \pi} \frac{z\left(i q_{2}+\epsilon\right)}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)} \frac{\left\langle\tilde{\eta}_{D}\left(i q_{1}+\epsilon\right) \tilde{\eta}_{S}\left(i q_{2}+\epsilon\right)\right\rangle_{c}}{R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime \prime}\left(i q_{2}+\epsilon\right)} \\
= & -\frac{\gamma\left(T_{1}-T_{2}\right) k_{1}}{m^{2}} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \int_{-\infty}^{\infty} \frac{d q_{2}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)} \frac{\left(i q_{2}+\epsilon\right)}{R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime \prime}\left(i q_{2}+\epsilon\right)} \frac{1}{\left(i q_{1}+i q_{2}+2 \epsilon\right)} \\
= & -\frac{1}{2} \frac{\gamma\left(T_{1}-T_{2}\right) k_{1}^{2}}{\gamma^{2}\left(k+k_{1}\right)+k_{1}^{2} m},
\end{aligned}
$$

which is already a well known result [10, 11].

## 3. Order 1 on $k_{3}$

There are two contributions to order 1 on $k_{3}$ : one from the quadratic term and another from the quartic one. The quadratic term reads,

$$
\begin{array}{r}
{\overline{\left\langle j_{12}\right\rangle}}_{12}=k_{1} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \cdots \int_{-\infty}^{+\infty} \frac{d q_{5}}{2 \pi} \frac{z\left(i q_{2}+\epsilon\right)}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)} \frac{2 k_{3}}{R^{\prime}\left(i q_{1}+\epsilon\right)} \frac{\left\langle\tilde{r}_{D}\left(i q_{3}+\alpha\right) \tilde{r}_{D}\left(i q_{4}+\alpha\right) \tilde{r}_{D}\left(i q_{5}+\alpha\right) \tilde{r}_{S}\left(i q_{2}+\epsilon\right)\right\rangle_{c}}{i q_{1}+\epsilon-\left(i q_{3}+i q_{4}+i q_{5}+3 \alpha\right)} \\
= \\
12 \gamma^{2} k_{1} k_{3} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \cdots \int_{-\infty}^{+\infty} \frac{d q_{5}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)} \frac{\left(i q_{2}+\epsilon\right)}{i q_{1}+\epsilon-\left(i q_{3}+i q_{4}+i q_{5}+3 \alpha\right)} \times \\
 \tag{B4}\\
\times \frac{1}{R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime}\left(i q_{3}+\alpha\right) R^{\prime}\left(i q_{4}+\alpha\right) R^{\prime}\left(i q_{5}+\alpha\right) R^{\prime \prime}\left(i q_{2}+\epsilon\right)} \frac{\left(T_{1}+T_{2}\right)\left(T_{1}-T_{2}\right)}{\left(i q_{3}+i q_{4}+2 \alpha\right)\left(i q_{5}+\alpha+i q_{2}+\epsilon\right)} \\
=\quad
\end{array}
$$

The quartic term reads,

$$
\begin{align*}
\overline{\left\langle j_{12}\right\rangle_{12}}= & -k_{3} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \cdots \int_{-\infty}^{\infty} \frac{d q_{4}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+i q_{3}+i q_{4}+2 \epsilon\right)} \times \\
= & \times\left\{\left(i q_{2}+\epsilon\right)\left\langle\tilde{r}_{D}\left(i q_{1}+\epsilon\right) \tilde{r}_{S}\left(i q_{2}+\epsilon\right) \tilde{r}_{D}\left(i q_{3}+\epsilon\right) \tilde{r}_{D}\left(i q_{4}+\epsilon\right)\right\rangle_{c}\right\} \\
= & -6 \gamma^{2} k_{3} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \ldots \int_{-\infty}^{\infty} \frac{d q_{4}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+i q_{3}+i q_{4}+2 \epsilon\right)} \times  \tag{B5}\\
& \times \frac{\left(i q_{2}+\epsilon\right)}{R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime}\left(i q_{3}+\alpha\right) R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime \prime}\left(i q_{2}+\epsilon\right)} \frac{\left(T_{1}+T_{2}\right)\left(T_{1}-T_{2}\right)}{\left(i q_{3}+i q_{4}+2 \alpha\right)\left(i q_{1}+i q_{2}+2 \epsilon\right)} \\
= & -\frac{3}{2} \frac{\gamma k_{1} k_{3}\left(T_{1}^{2}-T_{2}{ }^{2}\right)}{\left(k+2 k_{1}\right)\left[\gamma^{2}\left(k+k_{1}\right)+m k_{1}^{2}\right]} .
\end{align*}
$$

The total term reads,

$$
\begin{equation*}
\overline{\left\langle j_{12}^{(1)}\right\rangle}=-\frac{3}{2} \frac{\gamma^{3} k_{1} k_{3}\left(2 k+k_{1}\right)\left(T_{1}^{2}-T_{2}^{2}\right)}{\left(k+2 k_{1}\right)\left[m k^{2}+\gamma^{2}\left(k+k_{1}\right)\right]^{2}} . \tag{B6}
\end{equation*}
$$

By the relation $j_{12}=-\kappa \Delta T$, we obtain the expansion of the thermal conductance as,

$$
\begin{align*}
& \kappa=\frac{\gamma k_{1}^{2}}{\gamma^{2}\left(k+k_{1}\right)+k_{1}^{2} m}+\frac{3}{2} \frac{\gamma^{3} k_{1} k_{3}\left(2 k+k_{1}\right)\left(T_{1}+T_{2}\right)}{\left(k+2 k_{1}\right)\left[m k^{2}+\gamma^{2}\left(k+k_{1}\right)\right]^{2}}+\mathcal{O}\left(k_{3}^{2}\right)  \tag{B7}\\
& \kappa=\quad \kappa^{(0)}+\kappa^{(1)}+\mathcal{O}\left(k_{3}^{2}\right)
\end{align*}
$$

## Appendix C: Poisson Conductance

An interesting use of our formalism is to compare the result of Eq. (B7) with the case of Poisson noise. For Poisson we have [11],

$$
\begin{align*}
<\tilde{\eta}\left(s_{1}\right) \tilde{\eta}\left(s_{2}\right)>_{c} & =\frac{2 \gamma T}{s_{1}+s_{2}} \\
<\tilde{\eta}\left(s_{1}\right) \tilde{\eta}\left(s_{2}\right) \tilde{\eta}\left(s_{3}\right) \tilde{\eta}\left(s_{4}\right)>_{c} & =\frac{1}{\lambda} \frac{24 \gamma^{2} T^{2}}{s_{1}+s_{2}+s_{3}+s_{4}} \tag{C1}
\end{align*}
$$

where the expression for the fourth order cumulant can be checked by dimensional analysis and compared with that of reference [11].

The combinations $<\tilde{\eta}_{S, D} \tilde{\eta}_{S, D}>$ need to be reexamined. For the Poisson noise, they yield,

$$
\begin{array}{rlcc}
<\tilde{\eta}_{D}\left(s_{1}\right) \tilde{\eta}_{D}\left(s_{2}\right)>_{c} & = & \frac{2 \gamma\left(T_{1}+T_{2}\right)}{s_{1}+s_{2}} \\
<\tilde{\eta}_{S}\left(s_{1}\right) \tilde{\eta}_{S}\left(s_{2}\right)>_{c} & = & \frac{\gamma\left(T_{1}+T_{2}\right)}{2\left(s_{1}+s_{2}\right)} \\
<\tilde{\eta}_{S}\left(s_{1}\right) \tilde{\eta}_{D}\left(s_{2}\right)>_{c} & = & \frac{\gamma\left(T_{1}-T_{2}\right)}{s_{1}+s_{2}}  \tag{C2}\\
<\tilde{\eta}_{S}\left(s_{1}\right) \tilde{\eta}_{D}\left(s_{2}\right) \tilde{\eta}_{D}\left(s_{3}\right) \tilde{\eta}_{D}\left(s_{4}\right)>_{c} & = & \frac{1}{\lambda} \frac{12 \gamma^{2}\left(T_{1}+T_{2}\right)\left(T_{1}-T_{2}\right)}{s_{1}+s_{2}+s_{3}+s_{4}} .
\end{array}
$$

The zero-th order on $k_{3}$ is exactly the same as the Gaussian case. The first order can be illustrative and we shall calculate it in the following. The quadratic term reads,

$$
\begin{align*}
& \overline{\left\langle j_{12}\right\rangle_{12}}= k_{1} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \cdots \int_{-\infty}^{\infty} \frac{d q_{5}}{2 \pi} \frac{z\left(i q_{2}+\epsilon\right)}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)} \frac{2 k_{3}}{R^{\prime}\left(i q_{1}+\epsilon\right)} \frac{\left\langle\tilde{r}_{D}\left(i q_{3}+\alpha\right) \tilde{r}_{D}\left(i q_{4}+\alpha\right) \tilde{r}_{D}\left(i q_{5}+\alpha\right) \tilde{r}_{S}\left(i q_{2}+\epsilon\right)\right\rangle_{c}}{i q_{1}+\epsilon-\left(i q_{3}+i q_{4}+i q_{5}+3 \alpha\right)} \\
&=\quad 24 \lambda \gamma^{2} k_{1} k_{3} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \lim _{\alpha \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \cdots \int_{-\infty}^{\infty} \frac{d q_{5}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+2 \epsilon\right)} \frac{\left(i q_{2}+\epsilon\right)}{i q_{1}+\epsilon-\left(i q_{3}+i q_{4}+i q_{5}+3 \alpha\right)} \times \\
& \times\left(i q_{2}+\epsilon\right) \frac{\left(T_{1}+T_{2}\right)\left(T_{1}-T_{2}\right)}{\left(i q_{3}+i q_{4}+2 \alpha+i q_{1}+i q_{2}+2 \epsilon\right)} \\
&=\quad-18 \gamma^{2} \frac{k_{1} k_{3}}{\lambda} \frac{\left(8 k^{2} \gamma^{2} m+20 \gamma^{2} k m k_{1}+6 k \gamma^{4}-9 \gamma^{2} m k_{1}^{2}-4 k m^{2} k_{1}^{2}-9 m^{2} k_{1}^{3}\right)\left(T_{1}^{2}-T_{2}^{2}\right)}{\left[\gamma^{2}\left(k+k_{1}\right)+m k^{2}\right]\left[6 \gamma^{2}\left(2 k+3 k_{1}\right)+16 k^{2} m+72 m k k_{1}+81 m k_{1}^{2}\right]\left(3 \gamma^{4}+4 \gamma^{2} k m+4 \gamma^{2} m k_{1}+m^{2} k_{1}^{2}\right)} \tag{C3}
\end{align*}
$$

The quartic term reads,

$$
\begin{align*}
\overline{\left\langle j_{12}\right\rangle_{14}}= & -k_{3} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \cdots \int_{-\infty}^{\infty} \frac{d q_{4}}{2 \pi} \frac{z\left(i q_{2}+\epsilon\right)}{z-\left(i q_{1}+i q_{2}+i q_{3}+i q_{4}+2 \epsilon\right)}\left\langle\tilde{r}_{D}\left(i q_{1}+\epsilon\right) \tilde{r}_{S}\left(i q_{2}+\epsilon\right) \tilde{r}_{D}\left(i q_{3}+\epsilon\right) \tilde{r}_{D}\left(i q_{4}+\epsilon\right)\right\rangle_{c} \\
= & -12 \lambda_{0} \gamma^{2} k_{3} \lim _{z \rightarrow 0} \lim _{\epsilon \rightarrow 0} \int_{-\infty}^{\infty} \frac{d q_{1}}{2 \pi} \cdots \int_{-\infty}^{\infty} \frac{d q_{4}}{2 \pi} \frac{z}{z-\left(i q_{1}+i q_{2}+i q_{3}+i q_{4}+2 \epsilon\right)} \frac{1}{R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime}\left(i q_{3}+\alpha\right) R^{\prime}\left(i q_{4}+\epsilon\right) R^{\prime \prime}\left(i q_{2}+\epsilon\right)} \\
& \times \frac{1}{R^{\prime}\left(i q_{1}+\epsilon\right) R^{\prime}\left(i q_{3}+\alpha\right) R^{\prime}\left(i q_{4}+\alpha\right) R^{\prime}\left(i q_{5}+\alpha\right) R^{\prime \prime}\left(i q_{2}+\epsilon\right)} \frac{\left(T_{1}+T_{2}\right)\left(T_{1}-T_{2}\right)}{\left(i q_{3}+i q_{4}+i q_{5}+3 \alpha+i q_{2}+\epsilon\right)} \\
=\quad & -18 \gamma^{2} \frac{k_{1} k_{3}}{\lambda} \frac{\left(8 k^{2} \gamma^{2} m+20 \gamma^{2} k m k_{1}+6 k \gamma^{4}-9 \gamma^{2} m k_{1}^{2}-4 k m^{2} k_{1}^{2}-9 m^{2} k_{1}^{3}\right)\left(T_{1}{ }^{2}-T_{2}^{2}\right)}{\left[\gamma^{2}\left(k+k_{1}\right)+m k^{2}\right]\left[6 \gamma^{2}\left(2 k+3 k_{1}\right)+16 k^{2} m+72 m k k_{1}+81 m k_{1}^{2}\right]\left(3 \gamma^{4}+4 \gamma^{2} k m+4 \gamma^{2} m k_{1}+m^{2} k_{1}^{2}\right)} . \tag{C4}
\end{align*}
$$

The total Poisson conductivity at order 1 on $k_{3}$ reads

$$
\begin{aligned}
\kappa_{\text {Poisson }}= & \frac{1}{2} \frac{\gamma k^{2}}{\gamma^{2}\left(k_{l}+k\right)+k^{2} m}+\frac{3}{2} \frac{\gamma^{3} k_{1} k_{3}\left(2 k+k_{1}\right)\left(T_{1}+T_{2}\right)}{\left(k+2 k_{1}\right)\left[m k^{2}+\gamma^{2}\left(k+k_{1}\right)\right]^{2}}+ \\
& +54 \gamma^{4} \frac{k_{1} k_{3}}{\lambda} \frac{\mathcal{N}}{\mathcal{D}}\left(T_{1}+T_{2}\right)+O\left(k_{3}^{3}\right) \\
= & \kappa^{(0)}+\kappa^{(1)}+\kappa^{(s)}+\mathcal{O}\left(k_{3}^{3}\right)
\end{aligned}
$$

where

$$
\begin{gather*}
\mathcal{N}=\begin{array}{c}
5 k \gamma^{2}+3 \gamma^{2} k_{1}+3 m k_{1}^{2}+4 k^{2} m+11 m k k_{1} \\
\mathcal{D}=\left[\gamma^{2}\left(k+k_{1}\right)+m k_{1}^{2}\right]\left[6 \gamma^{2}\left(2 k+3 k_{1}\right)+16 k^{2} m+72 m k k_{1}+81 m k^{2}\right] \times \\
\times\left[3 \gamma^{4}+4 \gamma^{2} m\left(k+k_{1}\right)+m^{2} k_{1}^{2}\right]
\end{array} .
\end{gather*}

[^1]:    ${ }^{1}$ Following our technique, it is possible to compute $\sigma_{j_{12}}^{2} \equiv\left\langle j_{12}^{2}\right\rangle-$ $\left\langle j_{12}\right\rangle^{2}$. We have set by such calculation because it demands a mathematical tour de force likely to yield a lengthy formula with little grasping information.
