Abstract

The Cartan-Maurer equations for any q -group of the A_{n-1}, B_n, C_n, D_n series are given in a convenient form, which allows their direct computation and clarifies their connection with the $q = 1$ case. These equations, defining the field strengths, are essential in the construction of q -deformed gauge theories. An explicit expression $\omega^i \wedge \omega^j = -Z^{ij}{}_{kl} \omega^k \wedge \omega^l$ for the q -commutations of left-invariant one-forms is found, with $Z^{ij}{}_{kl} \omega^k \wedge \omega^l \xrightarrow{q \rightarrow 1} \omega^j \wedge \omega^i$.

Key-words: Quantum gravity; Differential geometry; Quantum algebras.

Quantum groups [1]-[4] appear as a natural and consistent algebraic structure behind continuously deformed physical theories. Thus, in recent times, there have been various proposals for deformed gauge theories and gravity-like theories [5] based on q -groups.

Such deformations are interesting from different points of view, depending also on which theory we are deforming. For example, in quantized q -gravity theories space-time becomes noncommutative, a fact that does not contradict (Gedanken) experiments under the Planck length, and that could possibly provide a regularization mechanism [7,8]. On the other hand, for the q -gauge theories constructed in [6] spacetime can be taken to be the ordinary Minkowski spacetime, the q -commutativity residing on the fiber itself. As shown in [6], one can construct a q -lagrangian invariant under q -gauge variations. This could suggest a way to break the classical symmetry via a q -deformation, rather than by introducing ad hoc scalar fields. Note also that, unlike the $q = 1$ case, the q -group $U_q(N)$ is simple, thus providing a "quantum unification" of $SU(N) \otimes U(1)$.

In order to proceed from the algebraic q -structure to a dynamical q -field theory, it is essential to investigate the differential calculus on q -groups. Indeed this provides the q -analogues of the "classical" definitions of curvatures, field strengths, exterior products of forms, Bianchi identities, covariant and Lie derivatives and so on, see for ex. [9] for a review.

In this Letter we address and solve a specific problem: to find the Cartan-Maurer equations for any q -group of the A, B, C, D series in explicit form. These equations define the field strengths of the corresponding q -gauge theories [6]. The A_{n-1} case was already treated in [9], where the structure constants were given explicitly, and shown to have the correct classical limit.

To our knowledge, this problem has been tackled previously only in ref. [10]. There, however, the authors use (for the B, C, D q -groups) a definition for the exterior product different from the one introduced in refs [11], adopted in [12,13,9] and in the present Letter. As we will comment later, their choice leads to a more complicated scenario.

Quantum groups are characterized by their R -matrix, which controls the non-commutativity of the quantum group basic elements T^a_b (fundamental representation):

$$R^{ab}{}_{ef} T^e{}_c T^f{}_d = T^b{}_f T^a{}_e R^{ef}{}_{cd} \quad (1)$$

and satisfies the quantum Yang-Baxter equation

$$R^{a_1 b_1}{}_{a_2 b_2} R^{a_2 c_1}{}_{a_3 c_2} R^{b_2 c_2}{}_{b_3 c_3} = R^{b_1 c_1}{}_{b_2 c_2} R^{a_1 c_2}{}_{a_2 c_3} R^{a_2 b_2}{}_{a_3 b_3}, \quad (2)$$

a sufficient condition for the consistency of the "RTT" relations (1). Its elements depend continuously on a (in general complex) parameter q , or even on a set of parameters. For $q \rightarrow 1$ we have $R^{ab}{}_{cd} \xrightarrow{q \rightarrow 1} \delta_c^a \delta_d^b$, i.e. the matrix entries T^a_b

commute and become the usual entries of the fundamental representation. The q -analogue of $\det T = 1$, unitarity and orthogonality conditions can be imposed on the elements T^a_b , consistently with the RTT relations (1), see [3].

The (uniparametric) R -matrices for the q -groups of the A_{n-1}, B_n, C_n, D_n series can be found in ref. [3]. We recall the projector decomposition of the \hat{R} matrix defined by $\hat{R}^{ab}_{cd} \equiv R^{ba}_{cd}$, whose $q \rightarrow 1$ limit is the permutation operator $\delta^a_d \delta^b_c$:

A_n series:

$$\hat{R} = qP_+ - q^{-1}P_- \quad (3)$$

with

$$\begin{aligned} P_+ &= \frac{1}{q+q^{-1}}(\hat{R} + q^{-1}I) \\ P_- &= \frac{1}{q+q^{-1}}(-\hat{R} + qI) \\ I &= P_+ + P_- \end{aligned} \quad (4)$$

B_n, C_n, D_n series:

$$\hat{R} = qP_+ - q^{-1}P_- + \varepsilon q^{\varepsilon-N}P_0 \quad (5)$$

with

$$\begin{aligned} P_+ &= \frac{1}{q+q^{-1}}[\hat{R} + q^{-1}I - (q^{-1} + \varepsilon q^{\varepsilon-N})P_0] \\ P_- &= \frac{1}{q+q^{-1}}[-\hat{R} + qI - (q - \varepsilon q^{\varepsilon-N})P_0] \\ P_0 &= \frac{1-q^2}{(1-\varepsilon q^{N+1-\varepsilon})(1+\varepsilon q^{\varepsilon-N+1})}K \\ K^{ab}_{cd} &= C^{ab}C_{cd} \\ I &= P_+ + P_- + P_0 \end{aligned} \quad (6)$$

where $\varepsilon = 1$ for B_n, D_n , $\varepsilon = -1$ for C_n , and N is the dimension of the fundamental representation T^a_b , i.e. $N = 2n + 1$ for B_n and $N = 2n$ for C_n, D_n . C_{ab} is the q -metric, and C^{ab} its inverse (cf. ref. [3]).

From (3) and (5) we read off the eigenvalues of the \hat{R} matrix, and deduce the characteristic equations:

$$(\hat{R} - qI)(\hat{R} + q^{-1}I) = 0 \quad \text{for } A_{n-1} \quad (\text{Hecke condition}) \quad (7)$$

$$(\hat{R} - qI)(\hat{R} + q^{-1}I)(\hat{R} - \varepsilon q^{\varepsilon-N}I) = 0, \quad \text{for } B_n, C_n, D_n \quad (8)$$

The differential calculus on q -groups, initiated in refs [11], can be entirely formulated in terms of the R matrix. The general constructive procedure can be found in ref. [12], or, in the notations we adopt here, in ref. [9].

As discussed in [11] and [12], we can start by introducing the (quantum) left-invariant one-forms ω_a^b , whose exterior product

$$\omega_{a_1}^{a_2} \wedge \omega_{d_1}^{d_2} \equiv \omega_{a_1}^{a_2} \otimes \omega_{d_1}^{d_2} - \Lambda_{a_1 d_1}^{a_2 d_2} |_{c_2 b_2}^{c_1 b_1} \omega_{c_1}^{c_2} \otimes \omega_{b_1}^{b_2} \quad (9)$$

is defined by the braiding matrix Λ :

$$\Lambda_{a_1 d_1}^{a_2 d_2} |_{c_2 b_2}^{c_1 b_1} \equiv d^{f_2} d_{c_2}^{-1} \hat{R}^{b_1 f_2} |_{c_2 g_1} (\hat{R}^{-1})^{c_1 g_1} |_{a_1 e_1} (\hat{R}^{-1})^{a_2 e_1} |_{d_1 g_2} \hat{R}^{d_2 g_2} |_{b_2 f_2} \quad (10)$$

For $q \rightarrow 1$ the braiding matrix Λ becomes the usual permutation operator and one recovers the classical exterior product. Note that the "quantum cotangent space" Γ , i.e. the space spanned by the quantum one-forms ω_a^b , has dimension N^2 , in general bigger than its classical counterpart ($\dim \Gamma = N^2$ only for the $U_q(N)$ groups). This is necessary in order to have a bicovariant bimodule structure for Γ (cf. ref. ([10])). The same phenomenon occurs for the q -Lie generators defined below. For these, however, one finds restrictions (induced by the conditions imposed on the T^a_b elements) that in general reduce the number of independent generators. Working with N^2 generators is more convenient, since the nice quadratic relations (16) of the q -Lie algebra become of higher order if one expresses them in terms of a reduced set of independent generators. For a discussion see [13].

The relations (7) and (8) satisfied by the \hat{R} matrices of the A and B, C, D series respectively reflect themselves in the relations for the matrix Λ :

$$(\Lambda + q^2 I)(\Lambda + q^{-2} I)(\Lambda - I) = 0 \quad (11)$$

for the A q -groups, and

$$\begin{aligned} &(\Lambda + q^2 I)(\Lambda + q^{-2} I)(\Lambda + \varepsilon q^{\varepsilon+1-N} I)(\Lambda + \varepsilon q^{N-\varepsilon-1} I) \\ &\quad \times (\Lambda - \varepsilon q^{N+1-\varepsilon} I)(\Lambda - \varepsilon q^{-N-1+\varepsilon} I)(\Lambda - I) = 0 \end{aligned} \quad (12)$$

for the B, C, D q -groups, with the same ε as in (8). We give later an easy proof of these two relations.

Besides defining the exterior product of forms, the matrix Λ contains all the the information about the quantum Lie algebra corresponding to the q -group.

The exterior differential of a quantum k -form θ is defined by means of the bi-invariant element $\tau = \sum_a \omega_a^a$ as follows:

$$d\theta \equiv \frac{1}{q - q^{-1}} [\tau \wedge \theta - (-1)^k \theta \wedge \tau], \quad (13)$$

The normalization $\frac{1}{q - q^{-1}}$ is necessary in order to obtain the correct classical limit (see for ex. [9]). This linear map satisfies $d^2 = 0$, the Leibniz rule and commutes with the left and right action of the q -group [12].

The exterior differentiation allows the definition of the "quantum Lie algebra generators" $\chi_{a_2}^{a_1}$, via the formula [11]

$$da = \frac{1}{q - q^{-1}} [\tau a - a \tau] = (\chi_{a_2}^{a_1} * a) \omega_{a_1}^{a_2}. \quad (14)$$

where

$$\chi * a \equiv (id \otimes \chi)\Delta(a), \quad \forall a \in G_q, \chi \in G'_q \quad (15)$$

and Δ is the usual coproduct on the quantum group G_q , defined by $\Delta(T^a_b) \equiv T^a_c \otimes T^c_b$. The q -generators χ are linear functionals on G_q . By taking the exterior derivative of (14), using $d^2 = 0$ and the bi-invariance of $\tau = \omega_b^b$, we arrive at the q -Lie algebra relations [12], [9]:

$$\chi_{d_2}^{d_1} \chi_{c_2}^{c_1} - \Lambda_{e_1 f_1}^{e_2 f_2} |_{d_2 c_2}^{d_1 c_1} \chi_{e_2}^{e_1} \chi_{f_2}^{f_1} = C_{d_2 c_2}^{d_1 c_1} |_{a_1}^{a_2} \chi_{a_2}^{a_1} \quad (16)$$

where the structure constants are explicitly given by:

$$C_{a_2 b_2}^{a_1 b_1} |_{c_2}^{c_1} = \frac{1}{q - q^{-1}} [-\delta_{b_2}^{b_1} \delta_{c_1}^{a_1} \delta_{a_2}^{c_2} + \Lambda_{b c_1}^b |_{a_2}^{a_1} \delta_{a_2}^{b_1}]. \quad (17)$$

and $\chi_{d_2}^{d_1} \chi_{c_2}^{c_1} \equiv (\chi_{d_2}^{d_1} \otimes \chi_{c_2}^{c_1})\Delta$. Notice that

$$\Lambda_{a_1 d_1}^{a_2 d_2} |_{c_2}^{c_1} \delta_{c_2}^{b_1} = \delta_{a_1}^{b_1} \delta_{b_2}^{a_2} \delta_{d_1}^{c_1} \delta_{c_2}^{d_2} + O(q - q^{-1}) \quad (18)$$

because the R matrix itself has the form $R = I + (q - q^{-1})U$, with U finite in the $q \rightarrow 1$ limit, see ref. [3]). Then it is easy to see that (17) has a finite $q \rightarrow 1$ limit, since the $\frac{1}{q - q^{-1}}$ terms cancel.

The Cartan-Maurer equations are found by applying to $\omega_{c_1}^{c_2}$ the exterior differential as defined in (13):

$$d\omega_{c_1}^{c_2} = \frac{1}{q - q^{-1}} (\omega_b^b \wedge \omega_{c_1}^{c_2} + \omega_{c_1}^{c_2} \wedge \omega_b^b). \quad (19)$$

Written as above, the Cartan-Maurer equations are not of much use for computations. The right-hand side has an undefined $\frac{0}{0}$ classical limit. We need a formula of the type $\omega_{c_1}^{c_2} \wedge \omega_b^b = -\omega_b^b \wedge \omega_{c_1}^{c_2} + O(q - q^{-1})$ that allows to eliminate in (19) the terms with the trace ω_b^b (which has no classical counterpart) and obtain an explicitly $q \rightarrow 1$ finite expression.

The desired " ω -permutator" can be found as follows. We first treat the case of the A_{n-1} series. We apply relation (7) to the tensor product $\omega \otimes \omega$, i.e.:

$$(\Lambda^{ij}{}_{kl} + q^2 \delta_k^i \delta_l^j)(\Lambda^{kl}{}_{mn} + q^{-2} \delta_m^k \delta_n^l)(\Lambda^{mn}{}_{rs} - \delta_r^m \delta_s^n) \omega^m \otimes \omega^n = 0 \quad (20)$$

where we have used the adjoint indices $i \leftrightarrow a^b$, $j \leftrightarrow a^b$. Inserting the definition of the exterior product $\omega^n \wedge \omega^n = \omega^m \otimes \omega^n - \Lambda^{mn}{}_{rs} \omega^r \otimes \omega^s$ yields

$$(\Lambda^{ij}{}_{kl} + q^2 \delta_k^i \delta_l^j)(\Lambda^{kl}{}_{mn} + q^{-2} \delta_m^k \delta_n^l) \omega^m \wedge \omega^n = 0 \quad (21)$$

Multiplying by Λ^{-1} gives $(\Lambda + (q^2 + q^{-2})I + \Lambda^{-1}) \omega \wedge \omega$, or equivalently

$$\omega^i \wedge \omega^j = -Z^{ij}{}_{kl} \omega^k \wedge \omega^l \quad (22)$$

$$Z^{ij}{}_{kl} \equiv \frac{1}{q^2 + q^{-2}} [\Lambda^{ij}{}_{kl} + (\Lambda^{-1})^{ij}{}_{kl}]. \quad (23)$$

cf. ref. [9]. The ω -permutator $Z^{ij}{}_{kl}$ has the expected $q \rightarrow 1$ limit, that is $\delta_i^j \delta_k^l$.

There is another way to deduce the permutator Z , based on projector methods, that we will use for the B, C, D series. We first illustrate it in the easier A -case. Define

$$(P_I, P_J)_{a_1 d_1}^{a_2 d_2} |_{c_2 b_2}^{c_1 b_1} \equiv d^{f_2} d_c^{-1} \hat{R}^{b_1 f_2}_{c_2 g_1} (P_I)^{c_1 g_1}_{a_1 e_1} (\hat{R}^{-1})^{a_2 e_1}_{d_1 g_2} (P_J)^{d_2 g_2}_{b_2 f_2} \quad (24)$$

with $I, J = +, -$, the projectors P_+, P_- being given in (4). The (P_I, P_J) are themselves projectors, i.e.:

$$(P_I, P_J)(P_K, P_L) = \delta_{IK} \delta_{JL} (P_I, P_J) \quad (25)$$

Moreover

$$(I, I) = I \quad (26)$$

so that

$$(I, I) = (P_+ + P_-, P_+ + P_-) = (P_+, P_+) + (P_-, P_-) + (P_+, P_-) + (P_-, P_+) = I \quad (27)$$

Eq. (25) is easy to prove by using (24) and the relation, valid for all A, B, C, D q -groups:

$$d^f d_c^{-1} \hat{R}^{bf}_{cg} (\hat{R}^{-1})^{ce}_{ba} = \delta_a^f \delta_g^e \quad (28)$$

From the definition of Λ (10), using (3) and (24) we can write

$$\Lambda = (P_+, P_+) + (P_-, P_-) - q^{-2}(P_+, P_-) - q^2(P_-, P_+) \quad (29)$$

This decomposition shows that Λ has eigenvalues $1, q^{\pm 2}$, and proves therefore eq. (11). From the definition of the exterior product $\omega \wedge \omega = \omega \otimes \omega - \Lambda \omega \otimes \omega$ we find the action of the projectors (P_I, P_J) on $\omega \wedge \omega$:

$$(P_+, P_+) \omega \wedge \omega = (P_-, P_-) \omega \wedge \omega = 0 \quad (30)$$

$$(P_+, P_-) \omega \wedge \omega = (1 + q^{-2})(P_+, P_-) \omega \otimes \omega, \quad (P_-, P_+) \omega \wedge \omega = (1 + q^2)(P_-, P_+) \omega \otimes \omega \quad (31)$$

Using (27) and (30) we find :

$$\omega \wedge \omega = [(P_+, P_+) + (P_-, P_-) + (P_+, P_-) + (P_-, P_+)] \omega \wedge \omega = [(P_+, P_-) + (P_-, P_+)] \omega \wedge \omega \quad (32)$$

The ω -permutator is therefore $Z = -(P_+, P_-) - (P_-, P_+)$. We can express it in terms of the Λ matrix by observing that

$$(P_+, P_-) + (P_-, P_+) = -\frac{1}{q^2 + q^{-2}} (\Lambda + \Lambda^{-1}) + \frac{2}{q^2 + q^{-2}} ((P_+, P_+) + (P_-, P_-)) \quad (33)$$

as one deduces from (29). Note that Λ^{-1} is given in terms of projectors by the same expression as in (29), with $q \rightarrow q^{-1}$. When acting on $\omega \wedge \omega$ the $(P_+, P_+), (P_-, P_-)$ terms in (33) can be dropped because of (30), so that finally we arrive at eq. (23).

Because of the expansion (18) and a similar one for Λ^{-1} we easily see that the ω -permutator (23) can be expanded as

$$Z_{c_1 d_1}^{c_2 d_2} |_{a_2 b_2}^{a_1 b_1} \omega_{a_1}^{a_2} \wedge \omega_{b_1}^{b_2} = \omega_{d_1}^{d_2} \wedge \omega_{c_1}^{c_2} + (q - q^{-1}) W_{c_1 d_1}^{c_2 d_2} |_{a_2 b_2}^{a_1 b_1} \omega_{a_1}^{a_2} \wedge \omega_{b_1}^{b_2} \quad (34)$$

where W is a finite matrix in the limit $q \rightarrow 1$.

Let us return to the Cartan-Maurer eqs. (19). Using (22) we can write:

$$d\omega_{c_1}^{c_2} = \frac{1}{q - q^{-1}} (\omega_b^b \wedge \omega_{c_1}^{c_2} - Z_{c_1 b}^{c_2 b} |_{a_2 b_2}^{a_1 b_1} \omega_{a_1}^{a_2} \wedge \omega_{b_1}^{b_2}) \quad (35)$$

where Z is given by $(\Lambda + \Lambda^{-1})/(q^2 + q^{-2})$, cf. (23). Because of (34) we see that the ω_b^b terms disappear, and (35) has a finite $q \rightarrow 1$ limit.

We now repeat the above construction for the case of q -groups belonging to the B, C, D series.

Using (5) and (24) we find the following projector decomposition for the Λ matrix :

$$\begin{aligned} \Lambda = & (P_+, P_+) + (P_-, P_-) + (P_0, P_0) + \varepsilon q^{\varepsilon-1-N} (P_+, P_0) + \varepsilon q^{-(\varepsilon-1-N)} (P_0, P_+) \\ & - q^{-2} (P_+, P_-) - q^2 (P_-, P_+) - \varepsilon q^{N-\varepsilon-1} (P_0, P_-) - \varepsilon q^{-(N-\varepsilon-1)} (P_-, P_0) \end{aligned} \quad (36)$$

from which we read off the eigenvalues of Λ , and prove eq. (12). Proceeding as in the A case, we find the action of the projectors on $\omega \wedge \omega$:

$$(P_+, P_+) \omega \wedge \omega = (P_-, P_-) \omega \wedge \omega = (P_0, P_0) \omega \wedge \omega = 0 \quad (37)$$

$$\begin{aligned} (P_+, P_-) \omega \wedge \omega &= (1 + q^{-2}) (P_+, P_-) \omega \otimes \omega, \\ (P_-, P_+) \omega \wedge \omega &= (1 + q^2) (P_-, P_+) \omega \otimes \omega \end{aligned} \quad (38)$$

$$\begin{aligned} (P_-, P_0) \omega \wedge \omega &= (1 + \varepsilon q^{-(N-\varepsilon-1)}) (P_-, P_0) \omega \otimes \omega, \\ (P_0, P_-) \omega \wedge \omega &= (1 + \varepsilon q^{N-\varepsilon-1}) (P_0, P_-) \omega \otimes \omega \end{aligned} \quad (39)$$

$$\begin{aligned} (P_+, P_0) \omega \wedge \omega &= (1 - \varepsilon q^{\varepsilon-1-N}) (P_+, P_0) \omega \otimes \omega, \\ (P_0, P_+) \omega \wedge \omega &= (1 - \varepsilon q^{-(\varepsilon-1-N)}) (P_0, P_+) \omega \otimes \omega \end{aligned} \quad (40)$$

Again the sum of the projectors (P_I, P_J) yields the identity, so that we can write:

$$\omega \wedge \omega = [(P_+, P_-) + (P_-, P_+) + (P_-, P_0) + (P_0, P_-) + (P_+, P_0) + (P_0, P_+)] \omega \wedge \omega \quad (41)$$

where we have taken (37) into account. The ω -permutator Z is therefore given by

$$Z = -[(P_+, P_-) + (P_-, P_+) + (P_-, P_0) + (P_0, P_-) + (P_+, P_0) + (P_0, P_+)] \quad (42)$$

Can we express it in terms of odd powers of the Λ matrix, as in the case of the A groups? The answer is: only partially. In fact, by elementary algebra we find that

$$Z = -\alpha(\Lambda + \Lambda^{-1}) - \beta(\Lambda^3 + \Lambda^{-3}) - (1 - \alpha q_{-\epsilon N} - \beta q_{-3\epsilon N})[(P_\sigma, P_0) + (P_0, P_\sigma)] \quad (43)$$

with $\sigma \equiv \text{sgn}(\epsilon)$ and

$$\alpha = -\frac{1 + \beta q_\epsilon}{q_2} \quad (44)$$

$$\beta = \frac{q_2 - q_{\epsilon N-2}}{q_\epsilon q_{\epsilon N-2} - q_2 q_{3(\epsilon N-2)}} \quad (45)$$

$$q_n \equiv q^n + q^{-n} \quad (46)$$

Note: Λ^r is given by

$$\begin{aligned} \Lambda^r = & (P_+, P_+) + (P_-, P_-) + (P_0, P_0) + \epsilon^r [q^{r(\epsilon-1-N)}(P_+, P_0) + q^{-r(\epsilon-1-N)}(P_0, P_+)] \\ & + (-1)^r [q^{-2r}(P_+, P_-) + q^{2r}(P_-, P_+)] \\ & + (-\epsilon)^r [q^{r(N-\epsilon-1)}(P_0, P_-) + q^{-r(N-\epsilon-1)}(P_-, P_0)] \end{aligned} \quad (47)$$

Let us check that Z in (43) has a correct classical limit. We have $\alpha \xrightarrow{q \rightarrow 1} -\frac{9}{16}$ and $\beta \xrightarrow{q \rightarrow 1} \frac{1}{16}$; taking into account that the $(P_\sigma, P_0), (P_0, P_\sigma)$ terms disappear in the classical limit (cf. eq. (39), (40)) when applied to $\omega \wedge \omega$, we find the expected limit $Z^{ij}_{kl} \xrightarrow{q \rightarrow 1} \delta^i_k \delta^j_l$.

The Cartan-Maurer equations are deduced as before, and are given by (35) where now Z is the ω permutator of eq. (43) (Note: for explicit calculations the expression (42) is more convenient). Again the ω_b^b terms drop out since Z admits the expansion $Z_{c_1 d_1}^{c_2 d_2} |_{a_2 b_2}^{a_1 b_1} \omega_{a_1}^{a_2} \wedge \omega_{b_1}^{b_2} = -\omega_{d_1}^{d_2} \wedge \omega_{c_1}^{c_2} + O(q - q^{-1})$.

In conclusion: we have found an explicit (and computable) expression for the Cartan-Maurer equations of the B_n, C_n, D_n q -groups. This opens the possibility of constructing gauge theories of these q -groups, following the procedure used in [6] for the A_{n-1} q -groups.

Finally, let us comment on the differential calculus presented by the authors of ref. [10]. Their definition of exterior product in the B, C, D case differs from ours (and from the one adopted in [11,12,13]), and essentially amounts to require that $(P_\sigma, P_0)\omega \wedge \omega = 0$, $(P_0, P_\sigma)\omega \wedge \omega = 0$, besides (37). This has one advantage: the term $(P_\sigma, P_0) + (P_0, P_\sigma)$ disappears in the expression (43). The disadvantage is that the defining formula $\omega \wedge \omega = (I - \Lambda)\omega \otimes \omega$ does not hold any more for the B, C, D series, so that the general treatment of ref. [11] and the constructive procedure of ref.s [12] do not apply.
